

Confidence Level – Summary

The **Confidence Level** is a quality indicator that shows **how reliable a measured vital sign is**, rather than the value itself. It is determined based on factors such as **PPG signal quality, measurement conditions (lighting, movement, face detection), scan warnings, and the amount of high-quality data collected**.

The application assigns one of four confidence levels:

- **HIGH** – Result is highly reliable.
- **MEDIUM** – Result is usable but may be less reliable.
- **LOW** – Result may not be accurate due to poor measurement quality.
- **UNKNOWN** – The application could not determine a reliable result.

Confidence levels are included in the final scan report for these vital signs

- **Pulse Rate**
- **Respiration Rate**
- **SDNN**
- **Mean RRi**
- **PRQ**
- **RRI**
